What is an exception handling in Python?

Exception handling **allows you to separate error-handling code from normal code**. An exception is a Python object which represents an error. As with code comments, exceptions helps you to remind yourself of what the program expects. It clarifies the code and enhances readability. There are mainly two types of errors in python programming namely - **Syntax errors and Logical Errors or Exceptions**. Whenever we do not write the proper syntax of the python programming language (or any other language) then the python interpreter throws an error known as syntax error.
